

Restaurant Application Report

I designed the app to be very user friendly. Users can select the food item that they want to order by selecting the specific item and then entering the quantity of their order. Similarly, a customer can order several items at a time and all the items and bill would be calculated accordingly on the backend. It is easy to pay the tip amount to the server in terms of percentage. This application also divides the total amount of bill on the number of guests: It prompts the user for the number of guests and then divides the total bill amount including tax on the number of guests entered. It is capable of displaying the bill amount in two different ways; as total and as per guest.

Following are some key screenshots of the application:

As far as the limitations are concerned, this application does not have the ability to store or retrieve data from a database, so it does not have any communication with the database. I have tested it on several Microsoft Windows phones.
